```

Q2. Can you write an algorithm to **bubble sort** the following array { 30, 12, 18, 0, -5, 72, 424 }??

A2.

```

1 import java.util.Arrays;
2
3 public class BubbleSort {
4
5     public static void main(String[] args) {
6         Integer[] values = { 30, 12, 18, 0, -5,
7         int size = values.length;
8         System.out.println("Before:" + Arrays.de
9
10        for (int pass = 0; pass < size - 1; pass

```

11         for (int i = 0; i < size - pass - 1;
12             // swap if i > i+1
13             if (values[i] > values[i + 1])
14                 swap(values, i, i + 1);
15         }
16     }
17
18     System.out.println("After:" + Arrays.dee
19 }
20
21 private static void swap(Integer[] array, i
22     int temp = array[i];
23     array[i] = array[j];
24     array[j] = temp;
25 }
26 }

```

Q3. Is there a more efficient sorting algorithm than a bubble sort algorithm?

A3. Although **bubble-sort** is one of the simplest sorting algorithms, it's also one of the slowest. It has the $O(n^2)$ time complexity. Faster algorithms include **quick-sort** and **heap-sort**. The `Arrays.sort()` method uses the quick-sort algorithm, which on average has $O(n \cdot \log n)$ but can go up to $O(n^2)$ in a worst case scenario, and this happens especially with already sorted sequences.

```

1 import java.util.Arrays;
2
3 public class QuickSort {
4
5     public static void main(String[] args) {
6         Integer[] values = { 30, 12, 18, 0, -5,
7         System.out.println("Before:" + Arrays.de
8         Arrays.sort(values);
9         System.out.println("After:" + Arrays.dee
10     }
11 }

```

Q4. How will you **partition** the following numbers 7 3 6 8 2 9 5 4 around the pivotal number of 5 so that the lower values are in front of it and higher values are behind it?

A4. Approach 1: With two pointers as shown below

- [Career Making Know-](#)

7	3	6	8	2	9	5 (pivot)	4
^							^

Start two pointers, one at array index 0 and the other at array index 7, which is the last element in the array. Advance the left pointer forward until a value greater than the pivot (i.e. 5) is encountered. Advance the right pointer backwards until a value less than the pivot (i.e. 5) is encountered. In this case, the current left pointer value 7 is greater than pivot (i.e. 5) and the right pointer value 4 is less than the pivot (i.e. 5), so swap them as shown below before advancing as shown below with the shading. The pointers have also advanced to the next position. Also note that the left pointer has skipped the value "3" as it is less than pivot value "5". The right pointer has skipped the values "5" and "9" as they are equal and greater than the pivot value of "5" respectively.

4	3	6	8	2	9	5 (pivot)	7
		^		^			

The left pointer value 6 is greater than pivot (i.e. 5) and the right pointer value 2 is less than the pivot (i.e. 5), so swap them as shown below before advancing.

4	3	2	8	6	9	5 (pivot)	7
		^	^				

When the pointers are pointing to the same value as shown above, swap it with the pivot value as shown below.

4	3	2	5 (pivot)	6	9	8	7
		^	^				

As you can see now, the smaller values (or numbers) are in front of the pivot value "5" and higher values are behind it. This array is now called **partitioned**. The partitioning is used recursively by the quick sorting algorithm to sort elements. The above partitioning algorithm can be applied as shown below.

Partitioning numbers with two pointers

```

1 public class Partition {
2
3     public static int partition(int[] values, int
4         int rightIndex, int pivotIndex) {
5
6         int i = leftIndex;
7         int j = rightIndex;
8
9         while (i < j) {
10             //moving from left to right
11             while (i <= j && values[i] <= values
12                 i++;
13             //moving from right to left
14             while (j >= i && values[j] >= values
15                 j--;
16
17             if (i < j)
18                 swap(values, i, j);
19         }
20
21         //swap the current index value with the
22         swap(values, i, pivotIndex);
23         return i; // return
24     }
25
26     public static void swap(int[] values, int i
27         int temp = values[i];
28         values[i] = values[j];
29         values[j] = temp;

```

```

30     }
31
32     public static void main(String[] args) {
33         int[] values = { 7, 3, 6, 8, 2, 9, 5, 4 };
34         //pivot value is 5, left index value is
35         partition(values, 0, values.length - 1, values[5]);
36
37         //prints 4,3,2,5,6,9,8,7
38         for (int i = 0; i < values.length; i++)
39             System.out.print(values[i]);
40             if(i < values.length-1)
41                 System.out.print(",");
42     }
43 }
44 }

```

Approach 2: With a single pointer as shown below:

7	3	6	8	2	9	5 (pivot)	4
---	---	---	---	---	---	-----------	---

Send the pivot item to the back.

7	3	6	8	2	9	4	5 (pivot)
---	---	---	---	---	---	---	-----------

Move from left to right, and swap with the pointer if the current value is less than the pivot value "5". 3 is less than the pivot value of 5, so swap it with the pointer value. After swapping, move the pointer forward one index.

3	7	6	8	2	9	4	5 (pivot)
---	---	---	---	---	---	---	-----------

Skipping values "6" and "8" as they are greater than the pivot value of "5". 2 is less than the pivot value, so swap it with the current pointer value. After swapping, move the pointer forward one index.

3	2	6	8	7	9	4	5 (pivot)
---	---	---	---	---	---	---	-----------

4 is less than the pivot value, so swap it with the current pointer value and move the pointer forward one index.

3	2	4	8	7	9	6	5 (pivot)
---	---	---	---	---	---	---	-----------

No more smaller values than the pivot value of "5" can be found, so swap the pivot value with the current pointer value.

3	2	4	5 (pivot)	7	9	6	8
---	---	---	-----------	---	---	---	---

Partitioning numbers with a single pointer

```

1 public class Partition2 {
2
3     public static int partition(int[] values, int pivotIndex, int rightIndex) {
4
5         int pivotValue = values[pivotIndex];
6         // send pivot item to the back
7         swap(values, pivotIndex, rightIndex);
8
9         // keep track of where the front is
10

```

```

11     int index = leftIndex;
12     // check from the front to the back
13     for (int i = leftIndex; i < rightIndex;
14         {
15         // swap if the current value is less
16         if (values[i] < pivotValue) {
17             swap(values, i, index);
18             index++;
19         }
20     }
21
22     // put pivot item in the middle
23     swap(values, rightIndex, index);
24     return index; // return the c
25 }
26
27 public static void swap(int[ ] values, int i
28     int temp = values[i];
29     values[i] = values[j];
30     values[j] = temp;
31 }
32
33 public static void main(String[ ] args) {
34     int[ ] values = { 7, 3, 6, 8, 2, 9, 5, 4};
35     partition(values, 0, values.length - 1,
36
37     //prints 3,2,4,5,7,9,6,8
38     for (int i = 0; i < values.length; i++)
39         System.out.print(values[i]);
40         if(i < values.length-1)
41             System.out.print(",");
42     }
43 }
44 }

```

Q5. How would you go about applying the **QuickSort algorithm** to sort the values 7 3 6 8 2 9 5 4 without using the `Arrays.sort(...)`?

A5. The key steps involved are:

- **Partition** the array with respect to a random element.
- **Partition** the left part of the array.
- **Partition** the right part of the array.
- **Recursively perform the above steps** until the exit condition is reached.

Since this is a recursive algorithm, you need a terminating or exit condition that does not make a recursive call. The terminating condition is when the `rightIndex` is less than or equal to the `leftIndex`. If you don't know recursion, search this training for "**recursion**".

```

1 public class QuickSort {

```

```

2
3 //... partition and swap methods as shown be
4
5 public static int[ ] quicksort(int[ ] values
6
7 // This is a recursive algorithm and the
8 if (rightIndex > leftIndex) {
9 // partition the array with respect
10 int pivotIndex = (leftIndex + rightI
11 int newPivotIndex = partition(values
12
13 // partition the left part of the ar
14 quicksort(values, leftIndex, newPivo
15
16 // patition the right part of the arr
17 quicksort(values, newPivotIndex + 1,
18 }
19 return (int[ ]) values;
20 }
21
22 public static void main(String[ ] args) {
23 int[ ] values = { 7, 3, 6, 8, 2, 9, 5, 4
24 quicksort(values, 0, values.length - 1);
25
26 // prints 2,3,4,5,6,7,8,9
27 for (int i = 0; i < values.length; i++)
28 System.out.print(values[i]);
29 if (i < values.length - 1)
30 System.out.print(",");
31 }
32 }
33 }

```

Q. Did you make any assumptions in the above code?

A. Yes, the supplied array is not already sorted, it is a large array, and the sorting is always in ascending order.

Q6. Can you write a function that checks if a given array is already sorted either in ascending or descending order?

A6.

```

1 public class AlgorithmUtils {
2
3     public static boolean sorted(int[ ] input) {
4
5         if (input == null || input.length == 0)
6             throw new IllegalArgumentException("
7         }
8
9         boolean ascending = false;
10        int first = input[0];
11        int second = input[1];
12        // ascending
13        if (first < second)
14            ascending = true;
15
16        for (int i = 0; i < input.length-1; i++)
17            if ((ascending && input[i] > input[i
18                || (!ascending && input[i] <

```

```
19         return false;
20     }
21
22     return true;
23 }
24
25 //...
26 }
```

Q. How will you ensure that the above code is functioning it correctly?

A. By writing unit tests that cover positive scenarios like an array sorted in ascending order and an array sorted in descending order and also a negative scenario like an unsorted array. Also, test for exceptional conditions like a null or empty array.
