Share

Java multi-threading interview questions are very popular from beginner to experienced level candidates. Many struggle, including the so called experienced. That is why interviewers love this key area of concurrency management to assess your capabilities.

In Java, there are low level interfaces/classes to higher abstraction levels to implement concurrency

1) Implementing the **Runnable** or **Callable** interfaces & extending the **Thread** class.

2) **Executor services** with **completable future** objects.

3) **Fork and Join** framework.

4) **Actor models** like Akka.

Q1. Can you give some scenarios where you had used multi-threading in Java applications?

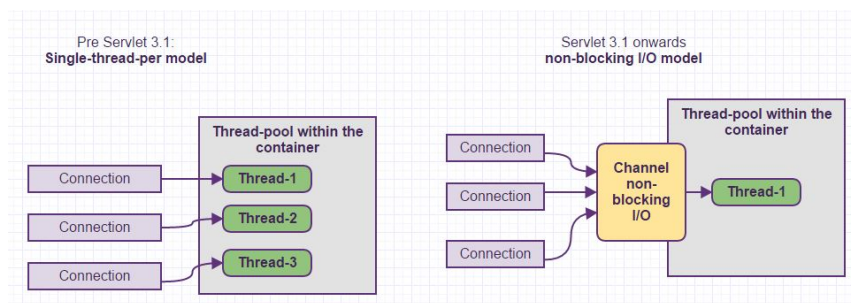

A1.

Scenario 1: Servlets are inherently multi-threaded

and each user will be using a thread from the thread pool.
The number of threads are configured via the web container of the application server. Servlet 3.1 supports non-blocking I/O for better throughput.

What is wrong with the thread-per-request model?

Pre Servlet 3.1 uses thread-per-request model, which limits the number of concurrent connections to the number of concurrently running JVM threads. Every thread introduces significant increase of memory footprint and CPU utilization via context switches. Servlet 3.1 rectifies this via non-blocking I/O. Fewer threads can be used in a pool to execute the request. NIO allows you to manage multiple channels (network connections or files) using only a single (or fewer) threads.

As a Java Architect

[Java architecture & design concepts](#)

Scenario 2: A MINA (i.e. a non-blocking I/O based) server with low level TCP protocol

to service 250+ petrol sites. The server supports the pay at the pump solution. The clients are C++ based and send fuel and credit card details to the server. A pool of reusable threads say 30 can be used to handle concurrent transactions.

Scenario 3: A Swing programmer deals with the following kinds of threads:

- a) Initial threads that execute the initial application code.
- b) The event dispatch thread, where all event-handling code is executed. Most code that interacts with the Swing framework must also execute on this thread.
- c) Worker threads, also known as background threads, where time-consuming background tasks are executed. For example, loading an image, retrieving and caching the data, processing any time consuming logic, etc.

Scenario 4: Asynchronous processing by spawning a worker thread

An online application with a requirement to produce time consuming reports or a business process (e.g. rebalancing accounts, aggregating hierarchical information, etc) could benefit from making these long running operations asynchronous. These tasks are performed on a separate worker thread. Once the reports or the long running business process is completed, the outcome can be communicated to the user via emails or asynchronously refreshing the web page via techniques known as “server push” or “client pull”. A typical example would be

- a) A user makes a request for an aggregate report or a business process like rebalancing his/her portfolios.
 - b) The user input can be saved to a database table for a separate process to periodically pick it up and process it asynchronously.
 - c) The user could now continue to perform other functionality of the website without being blocked.
 - d) A separate process running on the same machine or different machine can periodically scan the table for any entries and produce the necessary reports or execute the relevant business process. This could be a scheduled job that runs once during off-peak or every 10 minutes. This depends on the business requirement.
 - e) Once the report or the process is completed, notify the user via emails or making the report available online to be downloaded.
- A **CountDownLatch** can be used to wait on multiple threads performig different tasks. Once CountDownLatch reaches zero, the waiting threads can be released. For example 3

2. [Asynchronous processing in Java real life examples – part-2](#)

Scenario 5: Writing your own editor in Java where syntax highlighting is performed on a separate thread

To maximize the performance of the application, the CPU intensive syntax highlighting can be carried out on a separate worker thread whilst the user can use the editor.

Scenario 6: Java 7 fork and join to process computation intensive algorithms on a multi-core machine

Example. numbers = {1,2,3,4,5,6,7,8,9,10}, sum = 55;
process them using the fork and join feature introduced in Java 7.

Pseudo Code for Fork, Compute and Join

```

1
2 Result solve(Problem problem) {
3     if (problem is small) //e.g. smaller than ba
4         compute the problem
5     else {
6         split problem into chunks
7         fork new subtasks to solve each chunk
8         join all subtasks
9         compose result from subresults
10    }
11 }
12

```

Here is the Java code

```

1
2
3 package com.fork.join;
4
5 import java.util.ArrayList;
6 import java.util.Arrays;
7 import java.util.List;
8 import java.util.concurrent.RecursiveTask;
9
10 class SumTask extends RecursiveTask<Integer> {
11
12     static final int CHUNK_SIZE = 3; // execution b
13
14     Integer[] numbers;
15     int begin;
16     int end;
17
18     SumTask(Integer[] numbers, int begin, int end)
19     {
20         this.numbers = numbers;
21         this.begin = begin;
22         this.end = end;
23     }
24
25     @Override
26     protected Integer compute() {

```

```

26 //sums the given number
27 if (end - begin <= CHUNK_SIZE) {
28     int sum = 0;
29     List<Integer> processedNumbers = new ArrayLi
30     for(int i=begin; i < end; ++i) {
31         processedNumbers.add(numbers[i]); //just to
32         sum += numbers[i];
33     }
34
35     //tracking thread, numbers processed, and su
36     System.out.println(Thread.currentThread().ge
37         Arrays.asList(processedNumbers) + ", sum
38     return sum;
39 }
40
41 //create chunks, fork and join
42 else {
43     int mid = begin + (end - begin) / 2; //mid p
44     SumTask left = new SumTask(numbers, begin,
45     SumTask right = new SumTask(numbers, mid, en
46     left.fork(); //asynchronously exe
47     int leftAns = right.compute();
48     int rightAns = left.join(); //returns the a
49     System.out.println("leftAns=" + leftAns + "
50     return leftAns + rightAns;
51 }
52
53 }
54 }
55

```

Here is the test class with the main method

```

1 package com.fork.join;
2
3 import java.util.concurrent.ForkJoinPool;
4
5 public class SumTaskTest {
6
7     public static void main(String[] args) {
8         int numberOfCpuCores = Runtime.getRuntime().a
9         ForkJoinPool forkJoinPool = new ForkJoinPool(
10
11         Integer[] numbers = { 1, 2, 3, 4, 5, 6, 7, 8,
12         int sum = forkJoinPool.invoke(new SumTask(num
13
14         System.out.println(sum);
15     }
16 }
17 }
18

```

The output

```

1 ForkJoinPool-1-worker-1 proceesing [[6, 7]], sum
2 ForkJoinPool-1-worker-3 proceesing [[8, 9, 10]],
3 leftAns=27 + rightAns=13
4 ForkJoinPool-1-worker-2 proceesing [[3, 4, 5]], s
5 ForkJoinPool-1-worker-0 proceesing [[1, 2]], sum

```

```
6 leftAns=12 + rightAns=3
7 leftAns=40 + rightAns=15
8 55
9
```

Q. Where to use fork/join as opposed to using the **ExecutorService** framework?

A. The Fork/Join Framework in Java 7 is designed for work that can be broken down into smaller tasks and the results of those tasks combined to produce the final result. Multicore processors are now widespread across server, desktop, and laptop hardware. They are also making their way into smaller devices, such as smartphones and tablets. Fork/Join offers serious gains for solving problems that involve **recursion**.

The fork/join tasks should operate as “pure” in-memory algorithms in which no I/O operations come into play. Also, communication between tasks through shared state should be avoided as much as possible, because that implies that locking might have to be performed. Ideally, tasks communicate only when one task forks another or when one task joins another.

ExecutorService continues to be a fine solution for many concurrent programming tasks, and in programming scenarios in which recursion is vital to processing power, it makes sense to use Fork/join. This fork and join feature is used in Java 8 parallel stream processing with lambda expressions.

Scenario 7: RESTful service processing the request asynchronously by spawning a new thread

```
1 @Controller
2 @RequestMapping(value = "/v1/myapp/processor", p
3 public class MyAppEndpointControllerImpl impleme
4
5     @Inject
6     @Named("replayExecutor")
7     private Executor replayExecutor;
```

```

8
9     @Inject
10    private MyAppReplayService replayService;
11
12    @Override
13    @ResponseStatus(HttpStatus.ACCEPTED)
14    @RequestMapping(value = "/replay", method =
15    public void replayPendingRequests(
16        @RequestParam(required = false) final In
17
18        replayExecutor.execute(new Runnable() {
19            @Override
20            public void run() {
21                LOG.info("replayPendingRequests(
22                replayService.replayPendingReque
23            }
24        });
25    }
26
27 }
28
29

```

Configure the thread executor service via Spring JavaConfig.

```

1  @Configuration
2  @EnableWebMvc
3  @Import({
4      MyAppServiceConfiguration.class
5  })
6  @ComponentScan("com.mgl.wrap.ecm.enabler.endpoint
7  public class MyAppEndpointConfiguration extends
8
9      @Bean
10     public ExecutorService replayExecutor() {
11         return Executors.newSingleThreadExecutor
12     }
13
14     //...
15 }
16
17

```
