05: Q37-Q41 – Data lake & metadata interview questions & answers

Posted on [August 6, 2016](#) by [Arulkumaran Kumaraswamipillai](#)

Q37. What is a Data Lake?

A37. A **data lake** is a storage repository that holds a vast amount of structured, semi-structured, and unstructured **raw data** in its native format (aka pristine condition). The data structure and requirements are not defined until the data is needed. You can also call it a “raw data zone”.

In the Hadoop world, this raw data can be can ingested from the various sources via Apache Flume agents, Kafka, Apache NiFi, etc. The sources can be files, messages from a MOM (Message Oriented Middle-ware) like Websphere MQ, etc.

Q38. How does it differ from the data warehouse?

A38.

Data Warehouse	Data LAKE
Used by business users	Used by data scientists & analysts
Structured & processed data.	Structured, Semi-structured (e.g. XML), and unstructured (e.g. PDFs, word, images, etc) in raw. This unstructured nature of raw data gives better agility for data scientists & developers to re-configure their models & query on the fly. The raw data can be manipulated in a variety of ways.
schema-on-write. Before we can load data into a data warehouse, we first need to give it some shape and structure.	schema-on-read (aka late binding). In a data lake, you just load in the raw data, as-is, and when you're ready to use the data with a certain access pattern, you give it a shape and structure.
Expensive for large data volumes as run on specialized hardware.	Low cost storage as Hadoop runs on commodity hardware & Hadoop is open-source without any licensing fees. You also have community support.

Q39. How would you prevent a “data lake” quickly becoming a “data swamp”?

A39. You need to have an effective “data management” layer to prevent a “data lake” becoming a “data swamp”. The data management layer involves:

- 1) Extensible metadata registry: that provides data discovery & data lineage management functions. For example, “Cloudera Navigator metadata component”, “Loom” from Revelytix, etc. The metadata needs to capture security classification, data source info, created timestamp info, time to live info, source system, etc.
- 2) Tracking data transformations and lineage. Recording all the input and output transformation processes via MapReduce or Spark jobs.
- 3) RESTful APIs to discover metadata & data from other enterprise platforms & tools.
- 4) When you move data from the raw zone to “redefined/user” zones where a structure is applied on read to be used by data scientists, it is imperative to apply **data quality management**. Duplicate & bad data needs to be re-mediated & cleansed.
- 5) Develop repeatable and controlled processes to ingest and transform data into Hadoop.
- 6) Implement proper security, auditing & monitoring. E.g. Cloudera Navigator, Knox (Central authentication mechanism for Hadoop), Access control with LDAP, encryption of sensitive data, proper logging, etc.

Metadata, transformation lineage & quality of data are imperative to ensure that “data lake” does not become a “data swamp”.

Q40. How does the Cloudera Navigator Metadata Server extract metadata from the entities managed by Cloudera

Manager?

A40.

1) HDFS at the next scheduled run after an HDFS checkpoint. **Checkpointing** is a process of maintaining & persisting filesystem metadata in HDFS. It is crucial for NameNode recovery & restart. The filesystem metadata is stored in “fsimage” and the “edit log”. The “fsimage” is a file that represents a point-in-time snapshot of the filesystem’s metadata. The fsimage file format is very efficient to read, but not for making small incremental updates like renaming a single file. Hence, the “edit log” is used for recording the updates. This way, if the NameNode crashes, it can restore its state by first loading the “fsimage”, and then replaying all the operations from the “edit log”.

2) Hive/Sqoop 1 extracts table metadata from the **Hive Metastore server**.

3) MapReduce/Pig extracts the job metadata from the JobTracker.

4) YARN/Pig extracts from the Job History Server.

Q41. How would you go about “organizing your data lake” in HDFS?

A41. Firstly you can have 3 main directories.

1. Raw or Staging: to host all the original source files as they get ingested into the data lake. Each source system should have its own directory. For example:

```
1  
2 /data/raw/client1/day1  
3 /data/raw/client2/day2  
4 /data/stage/client1/20150523  
5
```

2. Cleansed or redefined: The raw or staged data needs to go through basic quality check. For example, trade files need to have valid symbol, price, and volume info. The cleansing

also include de-duplication of data. The cleansed data can be grouped by subject domains like finance, logs, sales, etc.

```
1  
2 /data/cleansed/client1/finance/day1  
3 /data/cleansed/client2/sales/day2  
4 /data/redefined/client1/logs/20150523  
5
```

3. Summarised or user defined: is the precomputed & optimized data that is used by the data scientists or analysts to be used for querying & reporting. For example, quarterly sales report, etc.

```
1  
2 /data/summarised/client1/sales/quarterly  
3 /data/summarised/client2/sales/monthly  
4 /data/user_defined/client1/bugs_report/2016_June  
5
```

In order to keep track of all the files and their corresponding directories, you need to maintain a repository of meta data that can be indexed (E.g. Apache Solr). The metadata info like security classification, data source info, ingestion timestamp, time to live, source system, file size, structure of the file, key columns, etc can be stored & indexed. An Oozie workflow can be created to scan the data files in HDFS, and updates or builds the SOLR index. The file meta data can also be maintained in an HBase/Hive database. We can query the metadata via Hive/Pig.
